

```
'''
```

In this task you are to write a mini python library(a python file with defined functions like the calculator you wrote in the previous class)

You are a Hockey coach of an olympic team. There are 10 players in your team. You need a mini-library that will help you manage your team better.

1. Define a dictionary(in ipynb notebook) of your team. The key must be a name and the value must be another dictionary with four field(keys):-

```
height - in metres
position(Left Back/Right Back/Middle Back/Goalkeeper/Front Left/Front Right/Front Center, Middle Center, Middle Right, Middle Left)
physique - (explosive, stamina, all-round)
nature - (realist/idealist)
age - in years
```

Example of two players dictionary is below(you must draft a team of your choice with 10 players)

```
{"sai":{"height":1.6, "position":"Front Left", "physique": "explosive", "nature":"idealist", "age":25}
, "aditya":{"height":1.5, "position":"Front Center", "physique": "all-round", "nature":"realist", "age":23}}
```

2. Write a separate python file "hockeyTeamManager.py". In this you must write the following functions:-

- Get the average height and age of a team.
- Get number of explosive/stamina/all-rounders you a team.(print in any format you desire)
- Find the position that two players play(if any)
- Find the position that no player plays(if any)
- Find the nature of the team. Based on number of realists and idealist if 70% of the team is of one side then conclude for that side

Example

```
if 7/10 are idealists then team is idealist.(same for realist)
if 6/10 or 5/10 are idealist or realists then team is a "mix"
```

- Find the overall physique of the team. The physique that occurs most number of times is the physique of the team
- If a new player is to be added into the team then find the maximum age allowed so that the average age of the team does not exceed 24 years.
- Write a print function to print in a clear way all the players with their respective positions in case coach wants to review the lineup.(example: <Name> Plays in position <position>" )
- Write a function to find all those athletes who are of a particular physique(take physique as argument to function)
- Write a function to find all those athletes who are of a particular nature(take nature as argument to function)

Example for above two(i,j)

```
>hockeyTeamManager.GetPlayersWithPhysique(playerDictionary, physiqueToFilter)
Should print name of players with physique are given in argument(explosive/stamina/all-round)
```

3. Now import this python file into the notebook and use all these functions one after the other.

Note: these functions must not be seen anywhere in the notebook. They should be written in the python file which you import into the notebook.
